| Page No.: |   |   |   |   |   |   |
| Date:     |   |   |   |   |   |   |

29/1/24

|             |                      |
|-------------|----------------------|
| Application | HTTP, DHCP, DNS, FTP |
| Transport   | TCP/UDP              |
| Network     | IP, RIP, BGP, ARP    |
| Data Link   | MAC                  |
| Physical    |                      |

TCP/IP stack

→ If your machine has 2 n/w adaptors → machine will have 2 IP addresses → MAC Address.

Given by manufac. of device  
Called Physical address.

MAC address → 48 bit long (Hexadecimal format)

Looks like: 1G : FA : 8B : 8C : 1G : 1B → 6 bytes or 48 bits

⇒ If there are 3 network interface cards ⇒ machine will have 3 MAC Addrs.

⇒ For broadcasting a message to all the systems:  
we use: FF : FF : FF : FF : FF : FF

⇒ IP Addr v/s MAC Addr

• ~~Name~~ Name v/s Institute Id  
MAC IP School Id  
Clg Id  
Company Id

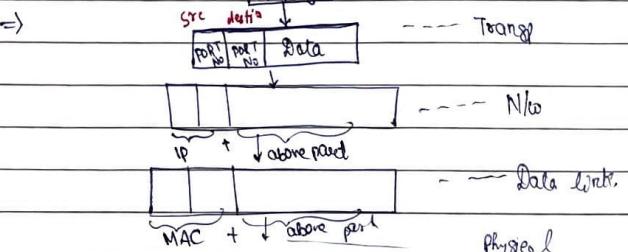

⇒ IP Address changes with change in network connected or even change if used for long time with same network.  
But MAC Address always remains same

\* 68.44.5.1 → 00000008 → 0 - 255 range for each [99]

⇒ PORT No :

https://www.google.com

(Port no: 443, Fixed)

| M | T | W | T | F | S | S |

DHCP:

Laptop wants to connect to `csev.google.com` using ethernet

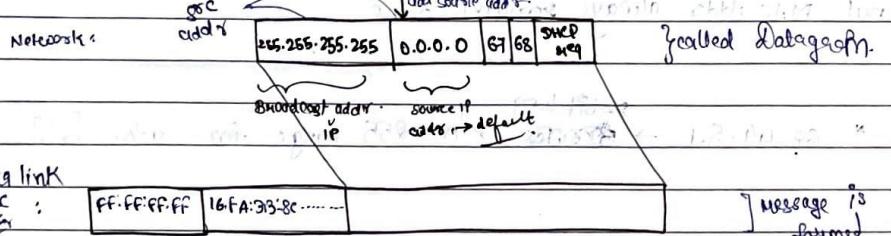

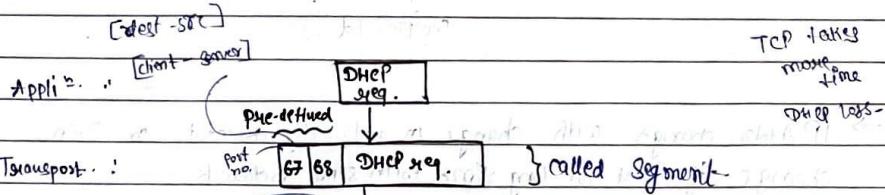

DHCP is required.

is a  
software client

DHCP  
server

↓  
has  
a port  
no.

follows DHCP guidelines of DHCP protocol.

Data link

MAC layer

→ This all is happening in switch

Port no: unique no. given to applic<sup>2</sup>.

| M | T | W | T | F | S | S |
|---|---|---|---|---|---|---|
|   |   |   |   |   |   |   |

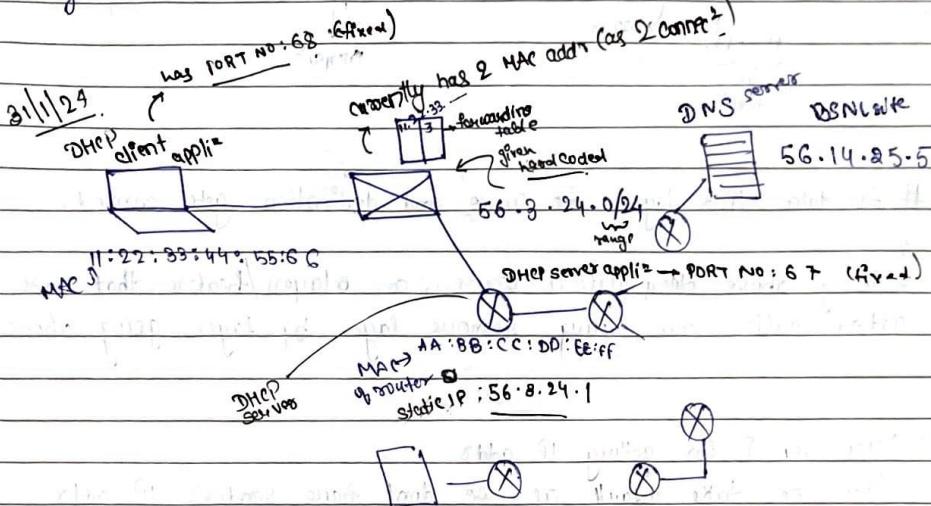

Page No. \_\_\_\_\_  
Date: \_\_\_\_\_

①

68.86.5.102 → the IP that the client should be assigned. This is selected from the pool given by ISP port

68.86.5.1 → of Router.

x.y.z.u

DHCP req.

| S: source   | D: destination | DHCP req. | msg | A          |
|-------------|----------------|-----------|-----|------------|
| segment     | segment        | SPN DPN   | msg | T Segment  |
| DHCP server | SIP DIP        | segment   |     | N Datagram |
| DM SM       | Dataframe      |           |     | D          |
|             |                |           |     | P          |

\* We get Mac address at NIC of each device

\* IP address is given by software by Network

\* Server at which applic<sup>2</sup> is running is called DHCP server.

# No. of MACs = No. of connection devices (Router) has = No. of MAC addresses

DHCP server provides IP address dynamically

DNS server stores domain names

Adding Addressing / headers → encapsulation

Removing headers → deapsulation.

Diagram illustrating the process of encapsulation and decapsulation:

Diagram illustrating the process of encapsulation and decapsulation:

Decaps:

Encaps:

This machine does not have Src IP & also Servers add so default will be added as broadcast to all

# At data link layer, ~~the~~ source and destination gets swapped.

# Going above decapsulation occurs, so @ layers/hands that were added earlier are being remove layer by layer going above

→ DHCP req is for getting IP addrs

↳ so we take default as we dont have sender's IP add<sup>r</sup> at that <sup>part</sup> (as its what we want), So at network layer in source we put default 0.0.0.0 IP add<sup>r</sup>.

# NIC adds mac. addr. or the controller attached to it.

DHCP is in router assumed for current examples

→ DHCP ~~sends~~ sends IP address as response which is available and made some additional info

|            |   |
|------------|---|
| 56.3.24.51 | → IP addr available to be returned.                       |
| 66.3.24.1  | → IP addr of router through msg has reached to DNS server |
| 56.14.25.5 | → IP addr of DNS server                                   |

Router is layer 3 device  
 Layer 2  
 Layer 3  
 Layer 4

DHCP  
Response : Server → device

Diagram illustrating a network communication flow:

- Response Frame:** Host B sends a response frame to host A.
- Host A Internal Processing:**
  - The frame is received by a router.
  - The source MAC address is 00:0C:29:41:00:00.
  - The destination MAC address is 00:0C:29:41:00:00.
  - The source IP address is 192.168.1.100.
  - The destination IP address is 192.168.1.101.
  - The frame is forwarded to the host A interface.
- Default Gateway:** Indicated as 192.168.1.1.

Now device have received DHCP response.

Forwarding Table consists of MAC address of Device, Router

→  $\rightarrow$  of Switch

MAC address    PORT NO

MAC address    PORT NO

↳ Physical port no., present on device

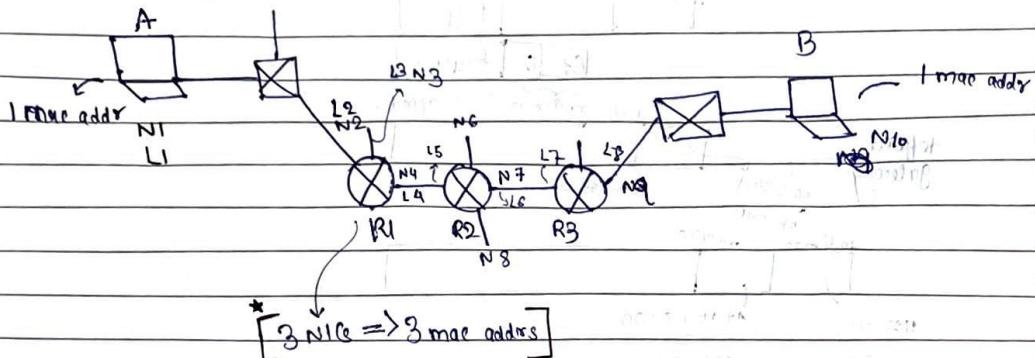

→ DHCP server v/s DNS server (Google it).  
↓  
assigns IP address to device which asks for it.

⇒ Routing table  
 for all addresses outside server

2/24

Look for this diagram in book.

|           |   |   |   |   |   |   |
|-----------|---|---|---|---|---|---|
| M         | T | W | T | F | S | S |
| Page No.: |   |   |   |   |   |   |
| Date:     |   |   |   |   |   |   |

How many IP addresses R2 has?  $\Rightarrow 4$

MAC addresses are also known as link-layer addresses or physical addresses.

$\Rightarrow$  N1  $\rightarrow$  Network layer addr = IP Addr  
L1  $\rightarrow$  Link layer addr = MAC-addr.

$\rightarrow$  Switch - mac-addr  $\Rightarrow$  do not connect two diff devices  
~~-~~  $\Rightarrow$  It only has ports.

\* we got N9 from flooding table  $\Rightarrow$  where it came from flooding table?  
from DHCP response

|           |   |   |   |   |   |   |
|-----------|---|---|---|---|---|---|
| M         | T | W | T | F | S | S |
| Page No.: |   |   |   |   |   |   |
| Date:     |   |   |   |   |   |   |

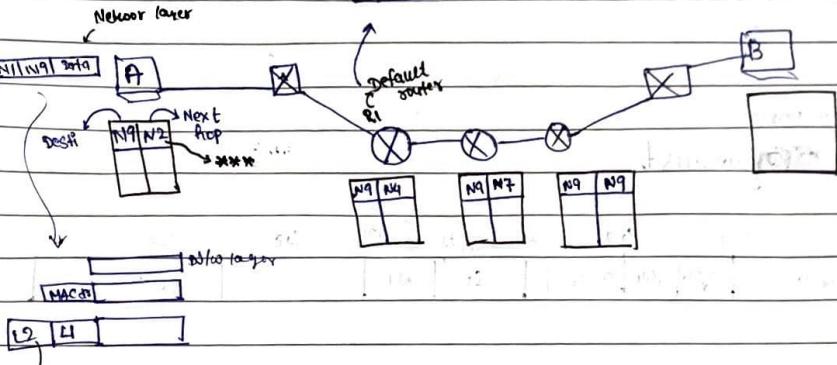

### Routing table

C contains entry of next device where data/packet is to be sent

say. N1  $\rightarrow$  N9  $\Rightarrow$  at A:

| Sec dest | N1 N9 | Dad 9 |
|----------|-------|-------|
|          |       |       |

(after decapsulation)

at R1: N9 is checked if its equal to current IP or not  
if not switching table is checked

| M         | T | W | T | F | S | S |
|-----------|---|---|---|---|---|---|
| Page No.: |   |   |   |   |   |   |
| Date:     |   |   |   |   |   |   |

| M         | T | W | T | F | S | S |
|-----------|---|---|---|---|---|---|
| Page No.: |   |   |   |   |   |   |
| Date:     |   |   |   |   |   |   |

## ARP (Address Resolution Protocol):

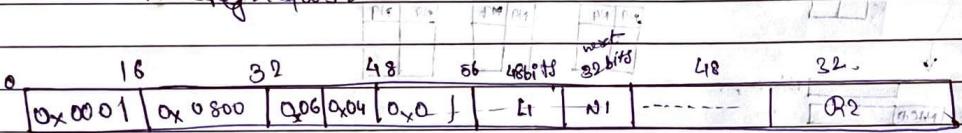

To send data from host A to host B, we need to know its MAC address.

(1) Takes the address → creates packet A to C.  $A \xrightarrow{\text{IP}} C$ .  $C \xrightarrow{\text{MAC}}$

Shivay

→ ARP response

ARP request

which protocol  
at data link  
layer  
(e.g.: ethernet)

For ex. If I want to send data to host B at IP 192.168.1.2, then at data link layer, take its

MAC address & write it in the destination field of the frame.

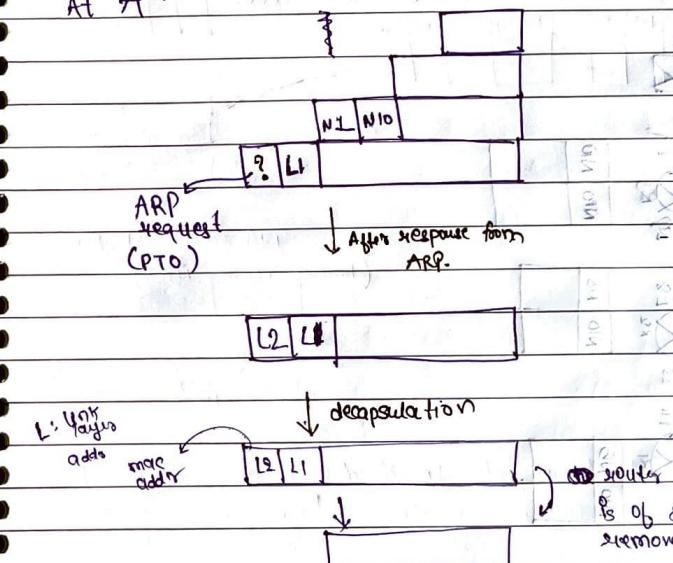

5/2/23

## Data Link Layer

|        |            |                                    |
|--------|------------|------------------------------------|
| App    | Port addrs | DNS @                              |
| Xproto | IP addrs   | domain name $\rightarrow$ IP addrs |
| N/W    | MAC addrs  | ARP: IP $\rightarrow$ MAC          |
| DL     |            |                                    |
| Phy    |            |                                    |

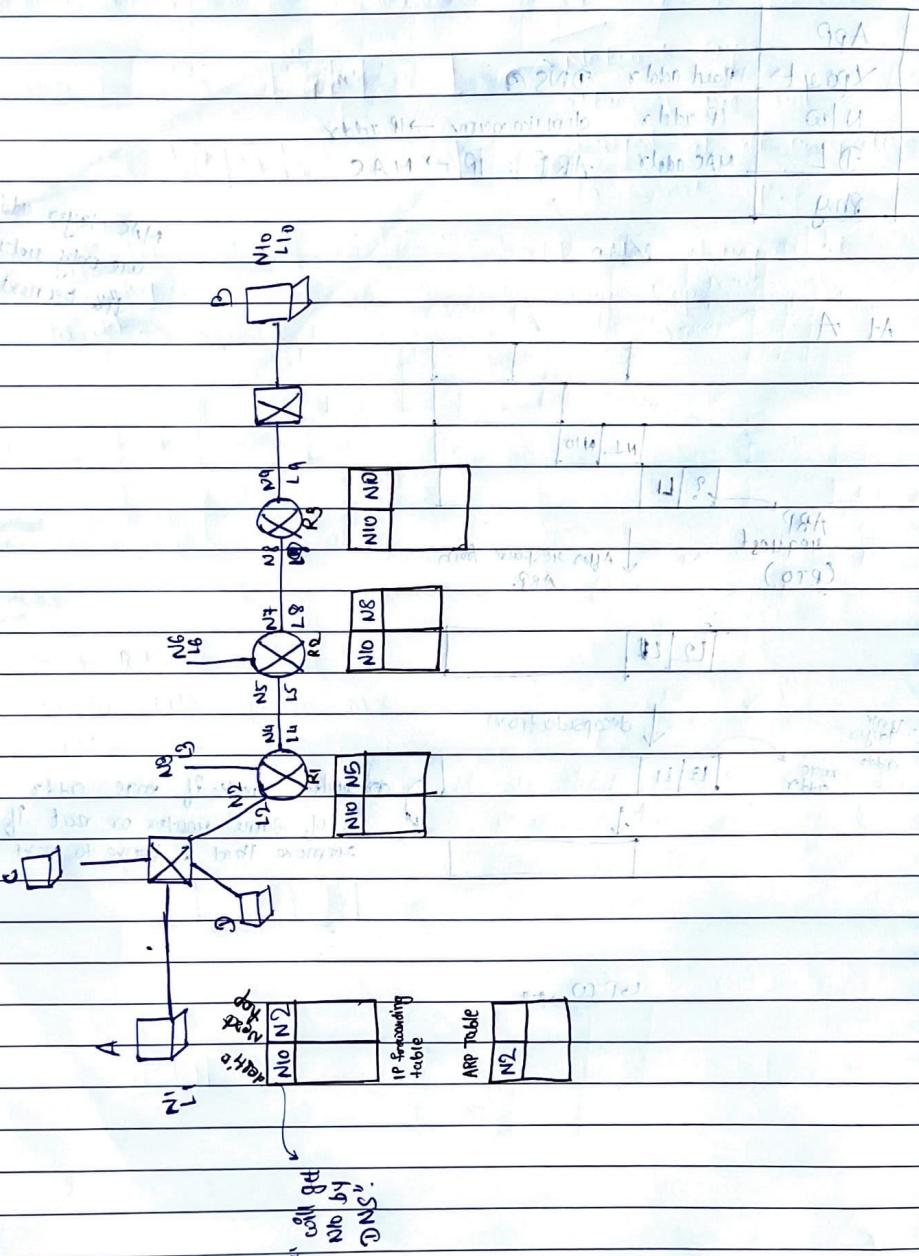

MAC layer addrs  
are only relevant  
till next hop.

At A:

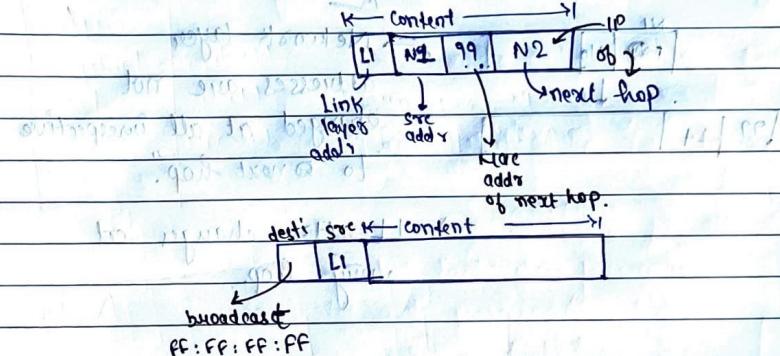

route checks if mac addrs  
is of same router or not. If so,  
remove that & move to next layer

PTO

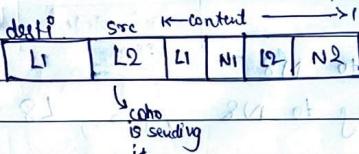

Returns mac adr. of next hop  
we give IP address of " " in request.

ARP request sent by A :

→ So now C & D will check & reject as req was not for them & then Router will send response.

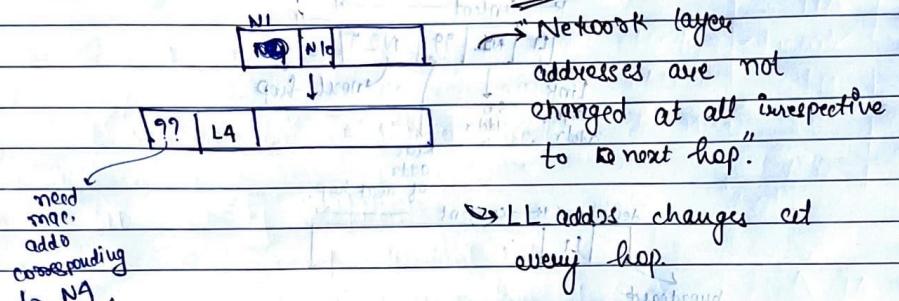

### [Response]

destin' problem (Khate hou)  
due to efficiency  
category

|           |   |   |   |   |   |   |
|-----------|---|---|---|---|---|---|
| M         | T | W | T | F | S | S |
| Page No.: |   |   |   |   |   |   |
| Date:     |   |   |   |   |   |   |

# # (R1 → R2)

when searched :

) check & remove : (remove (1))

) check if its meant for ib self  
if yes, remove & process

Process,

→ What if we don't have dest LL ?

↓ if there's no more,

we take IP add of next hop from Fwd Table & change the destination

coz lost final destination addy, so  
it's not possible.

listen to reading

→ check Fwd table

→ to go to N10 go to N8

need LL addr corresponding to N8 , i.e., L8

→ final

At receiver's end :

→ Received → 000 (No errors)

check for valid codeword

After validation

remove redundant bit &

send remaining two bits (00)

is send/fwd to upper layer

→ If bit error is found (000 → 010)

↳ Received : (say) 010

Not one of the valid  
code word

upper layer  
Not sent to valid word

→ If 2 bits changed (000 → 101)

↳ Received → 101

but is one of the valid even if there  
exists error

2 bit error can't be detected

To determine : "Hamming distance"

Hamming distance (0,0,0) needs permission by 0,0,0  
→ How many bits are different in two words given

$$d(010, 110) = 1$$

Take XOR → 010  
 $\oplus 110$   
 $\rightarrow 100$

# ~~Distance~~ Hamming distance b/w any two codewords is 2

If hamming distance =  $S+1$   
then No of errors detectable = S

Redundant bit must have some relation with data word,  
they are not randomly added.

# Parity bit :

code words

000

101

011

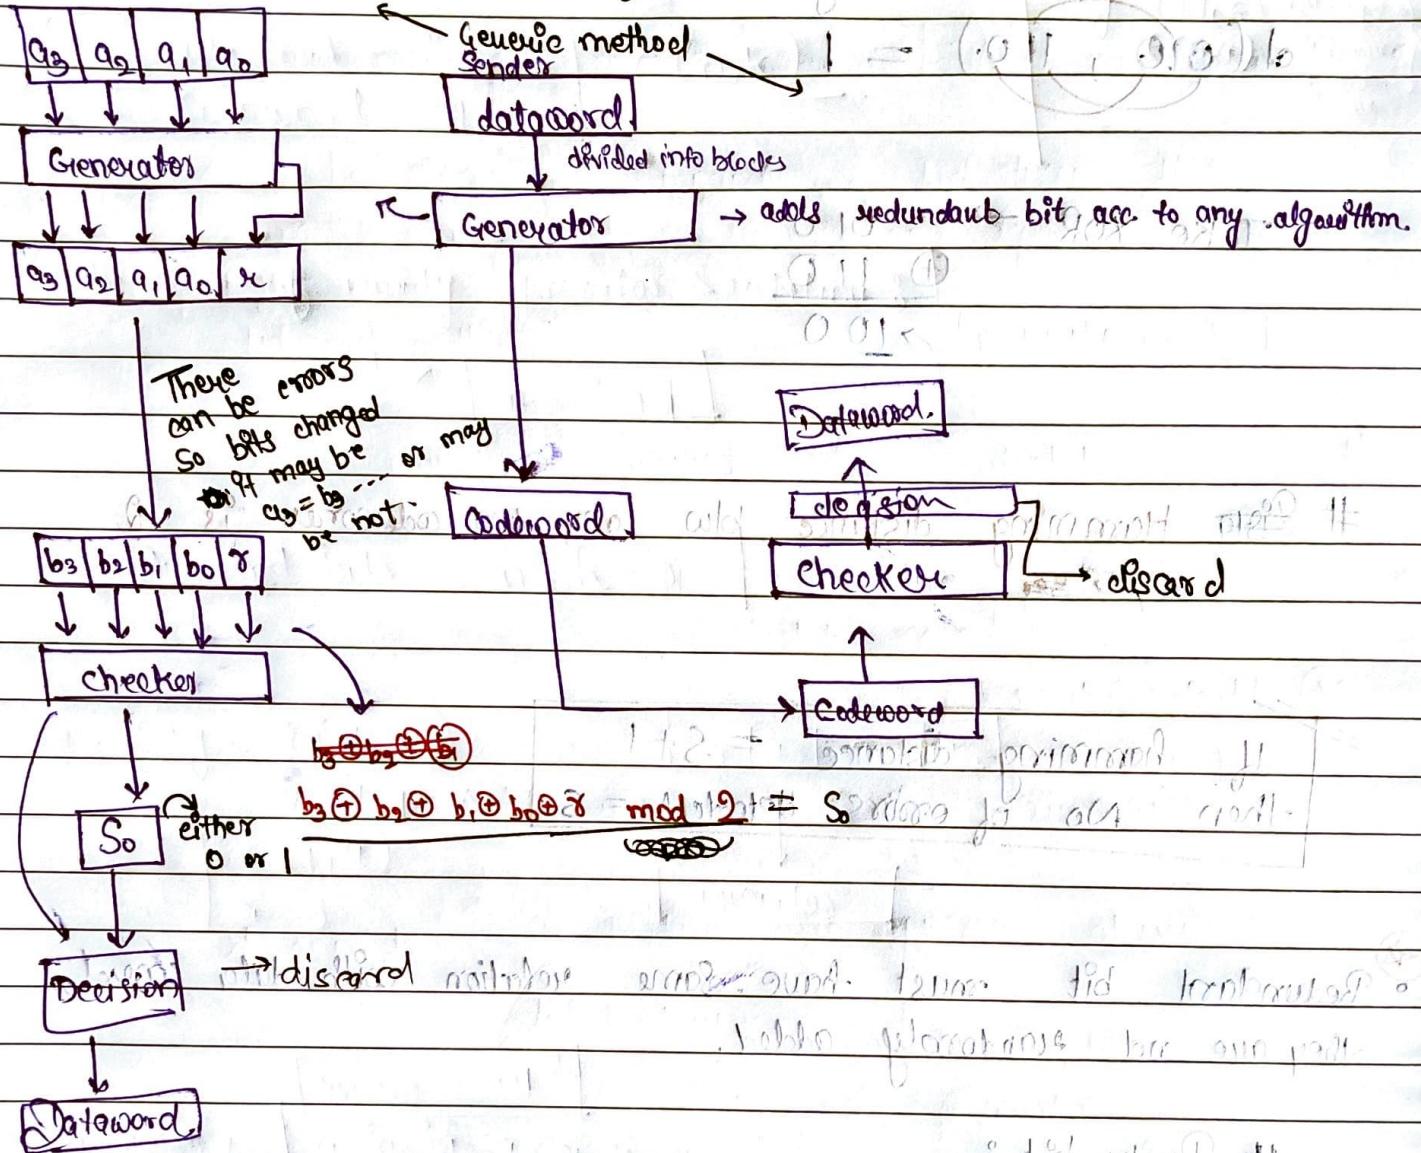

110

{ even 1's

Here even parity is considered

# Cyclic Redundancy check (CRC)

↳ most commonly used in LANs & WANs.

| M         | T | W | T | F | S | S |
|-----------|---|---|---|---|---|---|
| Page No.: |   |   |   |   |   |   |
| Date:     |   |   |   |   |   |   |

| M         | T | W | T | F | S | S |
|-----------|---|---|---|---|---|---|
| Page No.: |   |   |   |   |   |   |
| Date:     |   |   |   |   |   |   |

→ CRC :

$$\begin{matrix} \text{dataword} = k \\ \text{Code word} = m \end{matrix} \quad ] \quad \underline{\underline{C(n,k)}}$$

CRE : CC<sub>7,4</sub>) --

Parity :  $C(7,6)$  → Always  
 $C(5,4)$  difference  
 of ~~odd~~.

- In case of parity generator  $\Rightarrow$  relation?

$$n = R + 1$$

for party @. T = 1

$$\text{redundant bits} = n - k = r \quad \boxed{\text{For CRC } r = n - k}$$

Ex: say ~~for~~ for  $a_0, [a_0], a, [a_0]$

$$\begin{cases} C(7,4) \\ n = 3 \end{cases}$$

Wavy

$$\text{divisor} : 4 + 1$$

$$\begin{array}{c|ccccc} \alpha_3 & \alpha_2 & q_1 & q_0 & y_2 & y_1 & y_0 \\ \hline \text{known} & & & & & & \end{array}$$

Remainder  $r_2 \ r_1 \ r_0 \Rightarrow$  bits equal to  $x$  bits

1) dataword  $k = 20$  bits }  $\text{CRC} \Rightarrow k = 5$

codeword  $n = 25$  bits

$$\text{divisor} = 5+1=6$$

~~(1)~~ Ex: 101110000

$$\begin{array}{r}
 \text{now} \curvearrowleft \\
 \begin{array}{r}
 1001 \\
 + 1001 \\
 \hline
 10100
 \end{array}
 \end{array}$$

For modulo 2  $\Rightarrow$   
Subs  $\equiv ab \oplus x \text{ OR}$

011 → Remainder is actually the redundant bit

Code word to be transmitted: 101110001

Received at receiver end.

Divided by same divisor  $\rightarrow$  1001

if remainder = 0

remainder ≠ 0

## Correct code

empty is there.
